

HIREVIEW

Independent Development Declaration & Prior Art Establishment

Inventor IP Protection Document

Inventor: Vladyslav Vashchuk

Date of Document: July 7, 2026 (originally prepared) — updated July 9, 2026 to add Novel Implementation C

Contact: vladvashchuk2005@gmail.com | 571-544-1665

GitHub Repository: github.com/vashVlad/HireView

First Commit: June 2026

Document Purpose: Prior art establishment, independent development proof, employer IP claim protection

SECTION 1 — CRITICAL LEGAL NOTICE TO ANY REVIEWING PARTY

This document is prepared to formally establish that HireView was conceived, designed, and developed entirely by Vladyslav Vashchuk using personal resources, personal time, personal equipment, and personal financial investment, prior to and independent of any employer relationship. Any claim by any employer — including Brillio — to ownership of HireView or its constituent novel implementations would require clear written assignment from the inventor. Under U.S. law, inventions presumptively belong to the inventor. Ownership transfer must be in writing to be effective (USPTO MPEP). Simply employing someone does not transfer IP rights.

The 'hired to invent' doctrine (United States v. Dubilier Condenser Corp.) applies only where an employee is specifically hired to solve a particular technical problem or develop specific technology. Vladyslav Vashchuk was hired as a Consultant A3 in a talent acquisition function — not hired to invent AI recruiting software. HireView was conceived and substantially built before it was used in that context.

SECTION 2 — DECLARATION OF INDEPENDENT DEVELOPMENT

I, Vladyslav Vashchuk, declare the following to be true and accurate:

2.1 — Personal Resources Only

HireView was built exclusively using personal financial resources. All API costs (Anthropic Claude API), hosting costs (Vercel), and database costs (Supabase) were paid from personal funds. No employer resources, credits, or infrastructure were used at any point in development.

2.2 — Personal Equipment Only

All development was conducted on personal computers. No employer-issued equipment, employer networks, employer software licenses, or employer tools of any kind were used in the development of HireView.

2.3 — Personal Time Only

HireView was developed during personal time, outside of any work hours, work assignments, or employer-directed activities. No portion of HireView was built as part of any work assignment or at the direction of any employer.

2.4 — No Employer Trade Secrets Used

No employer trade secrets, confidential information, proprietary methods, or internal technical knowledge belonging to any employer were used in the conception or development of HireView. The system is built on publicly available technologies: Next.js, Supabase, Anthropic API (Claude), TypeScript, Tailwind CSS, and Vercel.

2.5 — Prior Invention Status

HireView's core architecture, novel implementations, and functional capabilities were conceived and substantially developed prior to any use of the system within a professional employment context. The system was used in a professional context only after it was independently built, at the inventor's own initiative.

2.6 — No Academic Institution Involvement

HireView has no connection to Susquehanna University or any other academic institution. No university resources, equipment, funding, supervision, or coursework were involved in its development. The university has no claim to this invention.

SECTION 3 — NOVEL TECHNICAL IMPLEMENTATIONS

The following implementations are identified as potentially novel and are documented here to establish conception date, reduce-to-practice date, and inventorship. This description is sufficient for a patent attorney to evaluate patentability.

IMPLEMENTATION A — Self-Improving Candidate Scoring via Recruiter Feedback Calibration

Date of Conception: June 2026

Date of Reduction to Practice: June 2026

Evidence: github.com/vashVlad/HireView — `lib/calibrationExamples.ts`, `lib/scoreCandidate.ts`, `app/api/history/[id]/calibrate/route.ts`

Description:

A closed-loop calibration system that improves AI candidate scoring accuracy over time through explicit recruiter feedback, without retraining or fine-tuning the underlying language model. The system operates as follows:

1. Resumes are scored 0-100 by a large language model (Claude) using a weighted evaluation framework: must-have skills weighted at 65%, nice-to-have skills at 35%.
2. A recruiter reviews results and optionally marks any screening as accurate (positive feedback) or inaccurate (corrective feedback). For corrective feedback, the recruiter provides a corrected score via a 0-100 slider and optional written reasoning.
3. Positive feedback: the resume text, job description, and original AI score are saved as a positive calibration example. Corrective feedback: the resume text, job description, recruiter-corrected score, and

reasoning are saved as a corrective calibration example.

4. On all subsequent scoring calls within the same project scope, relevant calibration examples are retrieved and injected into the scoring prompt as dynamic few-shot examples — demonstrating to the model what this specific recruiter considers accurate evaluation for this role type.

5. Calibration examples are scoped per user and per project, preventing cross-contamination between different recruiters or role types while enabling accumulating institutional memory within a role.

6. Resume text is re-extracted from stored files at calibration time, ensuring the full document context is captured, not a truncated display version.

Novel Characteristics:

- Calibration operates entirely at the prompt layer through dynamic few-shot injection — no model retraining, no training latency, immediate effect
- Captures both directional feedback (accurate/inaccurate) and magnitude correction (score slider) and qualitative reasoning — richer signal than binary systems
- User and project scoping prevents cross-contamination while enabling accumulating institutional memory
- Resume text is re-extracted from stored files at calibration time for full document fidelity
- The system is model-agnostic — the calibration layer functions identically regardless of which underlying LLM is used

IMPLEMENTATION B — Pre-Call Credibility Verification via Cross-Document Discrepancy Detection

Date of Conception: Mid-June 2026

Date of Reduction to Practice: Mid-June 2026

Evidence: github.com/vashVlad/HireView — Credibility Checker feature, Supabase Storage integration

Description:

A pre-call credibility verification workflow embedded within a recruiting pipeline that cross-references a candidate's resume against their LinkedIn PDF to surface discrepancies before a recruiter conducts a screening call. The system operates as follows:

1. After a resume is screened and added to the candidate pipeline, a recruiter optionally uploads a LinkedIn PDF for that candidate directly from the pipeline card.
2. Both documents — the original resume (retrieved from persistent storage) and the LinkedIn PDF — are processed through the same text extraction pipeline to ensure consistent quality.
3. A large language model cross-references both documents and surfaces specific discrepancies across: employment dates and gaps, job titles and seniority claims, skill listings, education credentials, and company names.
4. Results are categorized by type and assigned severity weighting. A credibility signal badge is displayed on the candidate's pipeline card, visible at a glance before any call is initiated.
5. The LinkedIn PDF is stored to persistent cloud storage and associated with the screening record, creating a permanent audit trail of the pre-call verification.

Novel Characteristics:

- Verification is embedded within the recruiting workflow — triggered from the pipeline card and displayed inline, not as a separate external tool
- Both documents processed through identical extraction pipeline for consistent text quality comparison
- Discrepancies categorized and severity-weighted, not returned as raw unstructured text
- Creates a persistent audit record associated with the candidate screening record
- Operates as a pre-call gate within an AI recruiting pipeline, not as a standalone background check

IMPLEMENTATION C — Identity-Blind Content Fingerprinting for Cross-Submission Fraud Detection

Date of Conception: July 2026

Date of Reduction to Practice: July 8, 2026 (extended July 9, 2026)

Evidence: github.com/vashVlad/HireView — `lib/generateFingerprint.ts`, `lib/resumeFingerprints.ts`, `supabase-migration-fingerprints.sql`, `supabase-migration-history-alert.sql`

Description:

A resume fraud detection system that identifies duplicate or fraudulently resubmitted candidates by matching exclusively on substantive resume content, while deliberately excluding every identity-revealing field from the comparison — so that the same qualifications resubmitted under a different name, contact detail, or claimed employer are still caught. The system operates as follows:

1. When a resume is screened and saved, a second large language model extraction call produces an identity-scrubbed content fingerprint: a normalized, hashed skills set; responsibility and duty vectors; quantified metric claims; and a career arc signature (the sequence of title and seniority progression) — all derived from resume content, none derived from name, contact information, or employer names.
2. The fingerprint is compared against existing fingerprints — scoped to the same project in the initial implementation — using similarity scoring (Jaccard similarity across the fingerprint's component sets) against a fixed threshold of 0.85.
3. When a match exceeds the threshold, both the newly submitted and the previously submitted screening records are flagged as duplicates, and a 'Duplicate Detected' indicator is surfaced on the candidate's pipeline card with a direct link to the matching prior submission.
4. Because matching never touches name, contact information, or company, the system continues to catch resumes resubmitted under a different identity — a recruiting fraud pattern that identity-based deduplication (matching by email, phone, or name) would miss entirely.
5. Extended July 9, 2026: the same fingerprint comparison was generalized across projects within a recruiting team's isolation boundary, surfacing a 'Previously Seen' signal when matching content reappears in a different role, and automatically escalating to a 'Known Fraud Pattern' signal when either matching submission already carried a same-project duplicate flag — reusing the existing fraud signal to determine severity rather than running an independent second detection pass.

Novel Characteristics:

- Fraud detection based entirely on substantive resume content and never on identity fields — deliberately defeats the common evasion technique of resubmitting the same qualifications under a different name or contact information

- Uses a multi-component content fingerprint (hashed skills set, responsibility vectors, metric claims, career arc signature) compared via similarity threshold, rather than exact-match or simple keyword overlap
- Escalation severity is derived by reusing an existing fraud signal from a related match rather than by running a second, independent detection pass
- Matching scope is architecturally tied to a data-isolation boundary (project, then team), so the same technique extends from single-project to cross-project detection without re-implementation
- Operates automatically as part of the standard screening save path — no separate manual step required of the recruiter

SECTION 4 — PRIOR INVENTIONS NOTICE TO EMPLOYER

Pursuant to standard Prior Inventions clauses in employment agreements (as recognized by Y Combinator, NVCA model documents, and major startup legal frameworks), this document serves as formal notice that HireView and its constituent implementations are prior inventions of Vladyslav Vashchuk, developed before and independently of any employer relationship in which HireView has been used.

HireView is hereby explicitly carved out of any invention assignment provision in any employment agreement signed by Vladyslav Vashchuk. Any employment agreement provision purporting to assign HireView to an employer is void with respect to this invention to the extent permitted by applicable law, including California Labor Code § 2870(a) and equivalent statutes, which void assignment provisions for inventions developed entirely on the employee's own time without employer resources, equipment, or trade secret information.

The four conditions required for independent inventor protection are satisfied:

CONFIRMED — Developed entirely on personal time

CONFIRMED — No employer equipment used

CONFIRMED — No employer supplies or facilities used

CONFIRMED — No employer trade secret information used

SECTION 5 — EVIDENCE TIMELINE

Date	Evidence	Significance
June 2026	First GitHub commit — github.com/vashVlad/HireView	Establishes earliest documented creation date
June 2026	Core resume screening implemented (scoreCandidate.ts)	Core novel implementation — conception date
June 2026	Calibration system implemented (calibrationExamples.ts)	Novel Implementation A — conception date
Mid-June 2026	Credibility Checker implemented	Novel Implementation B — conception date
June 29, 2026	Architecture redesign — project-based workflow	Reduction to practice documented in session log

Date	Evidence	Significance
July 6, 2026	Interview View feature deployed	Continued independent development
July 7, 2026	Multi-user auth, analytics, calibration UI deployed	Platform-level reduction to practice
July 7, 2026	280+ real candidate screenings processed at Brillio	Validated in real-world professional use
July 7, 2026	This document created and dated	Priority date establishment
July 8, 2026	Duplicate resume fingerprinting deployed (generateFingerprint.ts, resumeFingerprints.ts)	Novel Implementation C — conception + reduction to practice date
July 9, 2026	Cross-project history alert extension deployed, merged to main	Novel Implementation C — generalization documented
July 9, 2026	This document updated to add Novel Implementation C	Priority date established for Implementation C

SECTION 6 — RECOMMENDED PROTECTIVE ACTIONS

- Immediate: Email this document to vladvashchuk2005@gmail.com today — the email timestamp creates an independent date record outside of GitHub
- Immediate: Print, sign, and date a physical copy — keep in a secure personal location
- Within 30 days: Consult a patent attorney for provisional patent applications on Novel Implementation A (calibration system) and Novel Implementation C (identity-blind content fingerprinting) — cost approximately \$1,500-\$3,000 per application, provides 12 months of patent pending status
- Before any licensing or commercialization: Ensure no employment agreement signed with any employer contains a present-tense assignment clause (“hereby assigns”) that could capture HireView
- Ongoing: Maintain separate personal accounts, personal API keys, and personal infrastructure for all HireView development — never use employer resources

DECLARATION & SIGNATURE

I, Vladyslav Vashchuk, declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge and belief. This document was originally prepared on July 7, 2026 and updated on July 9, 2026 to add Novel Implementation C, and represents an accurate account of the independent development of HireView and its novel constituent implementations.
